David Harvey and Paul Zimmermann Short Division of Long Integers

ヘロン 人間 とくほ とくほ とう

3

Modern Computer Arithmetic Rocues on arbitrary-precision algorithms for efficiently epforming arithmetic operations curs a addition, multiplication and division, and their connections to topics such as modular arithmetic, greatest common divisors, the Fast Roufer Transform (FT), and the computation of elementary and special functions. Breat and Zimmermann present algorithms that are ready to implement in your Tavourite language, while keeping a high-level description and avoiding too low-level or machine-dependent details.

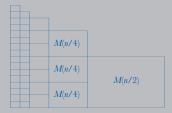

The book is intended for anyone interested in the design and implementation of efficient high-precision algorithms for computer anthmetic, and more generally efficient multiple-precision numerical algorithms. It may also be used in a graduate course in mathematics or computer science, for which exercises are included. These vary considerably in difficulty, from easy to small research projects, and expand on topics discussed in the text. Solutions are available from the autors.

Richard Brent is a Professor of Mathematics and Computer Science at the Australian National University, Canberra.

Paul Zimmermann is a Researcher at the Institut National de Recherche en Informatique et en Automatique (INRIA). Brent and Zimmermann Modern Computer Arithmetic

◆□> ◆□> ◆豆> ◆豆> ・豆 ・ のへで

- the most popular library for arbitrary-precision arithmetic
- distributed under a free license (LGPL) from gmplib.org
- main developer is Torbjörn Granlund
- contains several layers : mpn (arrays of words), mpz (integers), mpq (rationals), mpf (floating-point numbers)
- mpn is the low-level layer, with optimized assembly code for common hardware, and provides optimized implementations of state-of-the-art algorithms

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

An anonymous reviewer said :

What are the paper's weaknesses?

The resulting performance, in the referee's opinion, is only marginally better a standard exact-quotient algorithm in GMP. One can expect about 10% improvement. It seems to be a weak result for the sophisticated recursive algorithm with the big error analysis effort.

What is GNU MPFR?

- a widely used library for arbitrary-precision floating-point arithmetic
- distributed under a free license (LGPL) from mpfr.org
- main developers are Guillaume Hanrot, Vincent Lefèvre, Patrick Pélissier, Philippe Théveny and Paul Zimmermann
- contrary to GMP mpf, implements correct rounding and mathematical functions (exp, log, sin, ...)
- implements Sections 3.7 (Extended and extendable precisions) and 9.2 (Recommended correctly rounded functions) of IEEE 754-2008
- aims to be (at least) as efficient than other arbitrary-precision floating-point without correct rounding

・ロト ・ 同ト ・ ヨト ・ ヨト … ヨ

Assume we want to divide a > 0 of p bits by b > 0 of p bits, with a quotient c of p bits.

First write $a = m_a \cdot 2^{e_a}$ and $b = m_b \cdot 2^{e_b}$ such that :

• *m_b* has exactly *p* bits

•
$$2^{p-1} \le m_a/m_b < 2^p$$
 (*m_a* has $2p - 1$ or $2p$ bits)

The problem reduces to finding the *p*-bit correct rounding of m_a/m_b with the given rounding mode.

We do not assume that the divisor *b* is invariant, thus we do not allow precomputations involving *b*.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ● ○ ○ ○

The MPFR division routine relies on the (GMP) low-level division with remainder mpn_divrem.

mpn_divrem computes q and r such that

 $m_a = qm_b + r$ with $0 \le r < m_b$.

Since $2^{p-1} \le m_a/m_b < 2^p$, *q* has exactly *p* bits.

The correct rounding of the quotient is q or q + 1 depending on the rounding mode.

For rounding to nearest, if $r < m_b/2$, the correct rounding is q; if $r > m_b/2$, the correct rounding is q + 1.

◆□▶ ◆□▶ ★ □▶ ★ □▶ → □ → の Q ()

In GMP 5, the floating-point division (mpf_div) calls mpn_div_q, which only computes the (exact) quotient, and is faster (on average) than mpn_divrem or its equivalent mpn_tdiv_qr.

This is based on an approximate Barrett's algorithm, presented at ICMS 2006.

In most cases computing one more word of the quotient is enough to decide the correct rounding :

- pad the dividend with two zero low words
- pad the divisor with one zero low word
- one will obtain one extra quotient low word

Mulders' short product for polynomials (2000)

Short product : compute the upper half of $U \cdot V$, U and V having *n* terms (degree n - 1)

With Karatsuba's multiplication, can save 20% over a full product. Algorithm ShortMul.

Input: $U = \sum_{i=0}^{n-1} u_i \beta^i$, $V = \sum_{i=0}^{n-1} v_i \beta^i$, integer *n* **Output:** an integer approximation *W* of $UV\beta^{-n}$

1: **if** $n < n_0$ **then**

2:
$$W \leftarrow \text{ShortMulNaive}(U, V, n)$$

3: **else**

4: choose a parameter
$$k$$
, $n/2 + 1 \le k < n$, $\ell \leftarrow n - k$

5: write
$$U = U_1 \beta^{\ell} + U_0$$
, $V = V_1 \beta^{\ell} + V_0$

6: write
$$U = U'_1 \beta^k + U'_0$$
, $V = V'_1 \beta^k + V'_0$

7:
$$W_{11} \leftarrow \operatorname{Mul}(U_1, V_1, k) > 2k \text{ words}$$

8:
$$W_{10} \leftarrow \text{ShortMul}(U'_1, V_0, \ell) > \ell \text{ most significant words}$$

9:
$$W_{01} \leftarrow \text{ShortMul}(U_0, V'_1, \ell) > \ell \text{ most significant words}$$

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 ののの

10:
$$W \leftarrow \lfloor W_{11}\beta^{2\ell-n} \rfloor + W_{10} + W_{01}$$

Lemma

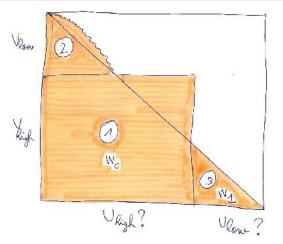

The output of Algorithm ShortMul satisfies

$$UV\beta^{-n} - (n-1) < W \le UV\beta^{-n}$$

(In other words, the error is less than n ulps.)

◆□ > ◆□ > ◆臣 > ◆臣 > ─臣 ─のへで

Mulders' short division (2000)

U is unknown V is known W = UV is known

- 1. estimate U_{high} from V_{high} and W_{high} , subtract $U_{\text{high}}V_{\text{high}}$ from W
- 2. compute $U'_{\text{high}}V_{\text{low}}$ and subtract from W
- 3. estimate U_{low} from V'_{high} and the remainder W

Algorithm ShortDiv. Input: $W = \sum_{i=0}^{2n-1} w_i \beta^i$, $V = \sum_{i=0}^{n-1} v_i \beta^i$, with $V \ge \beta^n/2$ **Output:** an integer approximation U of Q = |W/V|1: if $n < n_1$ then 2: $U \leftarrow \text{Div}(W, V)$ \triangleright Returns |W/V|3: else choose a parameter k, $n/2 < k \leq n, \ell \leftarrow n - k$ 4: write $W = W_1 \beta^{2\ell} + W_0$, $V = V_1 \beta^{\ell} + V_0$, $V = V_1' \beta^k + V_0'$ 5: $(U_1, R_1) \leftarrow \text{DivRem}(W_1, V_1)$ 6: write $U_1 = U'_1 \beta^{k-\ell} + S$ with $0 \le S < \beta^{k-\ell}$ 7: $T \leftarrow \text{ShortMul}(U'_1, V_0, \ell)$ 8: $W_{01} \leftarrow R_1 \beta^{\ell} + (W_0 \operatorname{div} \beta^{\ell}) - T \beta^k$ 9: while $W_{01} < 0$ do $(U_1, W_{01}) \leftarrow (U_1 - 1, W_{01} + V)$ 10: $U_0 \leftarrow \text{ShortDiv}(W_{01} \text{ div } \beta^{k-\ell}, V'_1, \ell)$ 11: return $U_1\beta^\ell + U_0$ 12:

◆□▶ ◆□▶ ◆三▶ ◆三▶ ● ○ ○ ○

Lemma

The output U of Algorithm ShortDiv satisfies, with $Q = \lfloor W/V \rfloor$:

 $Q \leq U \leq Q + 2(n-1).$

(In other words, the error is less than 2n ulps.)

◆□ > ◆□ > ◆臣 > ◆臣 > ─臣 ─のへで

The optimal cutoff k in ShortMul and ShortDiv heavily depends on n. There is no simple formula. Instead, we determine the best k(n) by tuning, for say n < 1000 words (about 20000 digits).

For ShortMul the best k varies between 0.5n and 0.64n, for ShortDiv it varies between 0.54n and 0.88n (for a particular computer and a given version of GMP).

Goal : given W and V, compute quotient Q and remainder R :

W = QV + R

- compute an approximation I of 1/V
- **2** compute an approximation Q = WI of the quotient
- (optional) compute the remainder R = W QV and adjust if necessary

When V is not invariant, computing 1/V is quite expensive :

- *ℓ*-fold reduction from Hasenplaugh, Gaubatz, Gopal (Arith'18, 2007) (LSB variant)
- for $\ell = 2$, HGG is exactly Karp-Markstein division (1997)

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 ののの

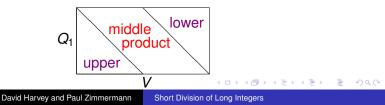

2-fold division (Karp-Markstein)

- **1** compute an approximation *I* of 1/V to n/2 words
- 2 deduce the upper n/2 words $Q_1 =$ ShortMul(W, I, n/2)
- **3** subtract $Q_1 V$ from W, giving W'
- deduce the lower n/2 words $Q_0 = \text{ShortMul}(W', I, n/2)$

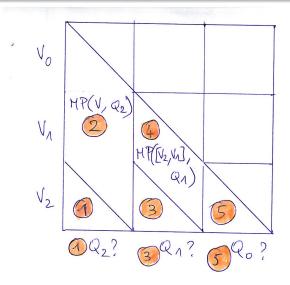

In step 3, $Q_1 V$ is a $(n/2) \times n$ multiplication, giving a 3n/2 product.

However, we know the upper n/2 words match with W, and we are not interested in the lower n/2 words.

This is exactly a *middle product* (Hanrot, Quercia, Zimmermann, 2004) :

The 3-fold division algorithm

The integer middle product (Harvey 2009)

Input : *X* of *m* words and *Y* of *n* words, with $m \ge n$

$$X = \sum_{i=0}^{m-1} x_i \beta^i, \qquad Y = \sum_{j=0}^{n-1} y_j \beta^j$$

Output :MP_{m,n}(X, Y) =
$$\sum_{\substack{0 \le i < m, 0 \le j < n \\ n-1 \le i+j \le m-1}} x_i y_j \beta^{i+j-n+1}$$

Lemma

$$|(XY - \beta^{n-1}MP_{m,n}(X, Y)) \mod \beta^m| < (n-1)\beta^n$$

Classical case : m = 2n - 1 with n^2 word-products.

Quadratic-time algorithms : n^2 .

Karatsuba-like middle product : $O(n^{1.58...})$.

FFT-variant : O(M(n)).

◎ ▶ ▲ 臣 ▶ ▲ 臣 ▶ ○ 臣 ● の Q ()

ℓ-fold Barrett division

Algorithm FoldDiv(ℓ), $\ell > 2$. Input: $W = \sum_{i=0}^{2n-1} w_i \beta^i$, $V = \sum_{i=0}^{n-1} v_i \beta^i$, with $V > \beta^n/2$, $W < \beta^n V$ **Output:** an integer approximation U of Q = |W/V|1: if *n* < *n*₂ then 2: return $U \leftarrow \text{Div}(W, V)$ 3: $k \leftarrow \lceil n/\ell \rceil$ 4: write $V = V_1 \beta^{n-(k+1)} + V_0$ \triangleright V₁ has k + 1 words 5: $I \leftarrow |(\beta^{2(k+1)} - 1)/V_1|$ 6: $r \leftarrow n$. $W_r \leftarrow W$. $U \leftarrow 0$ 7: while r > k + 1 do \triangleright invariant : $0 < W_r < \beta^r V$ 8: $Q_r \leftarrow \text{ShortMul}(W_r \text{ div } \beta^{n+r-(k+1)}, I, k+1)$ 9: $Q_r \leftarrow \min(Q_r, \beta^{k+1} - 1)$ 10: $T_r \leftarrow \operatorname{MP}_{r+1 \ k+1}(V \operatorname{div} \beta^{n-r}, Q_r)$ 11: $W_{r-k} \leftarrow (W_r - T_r \beta^{n-1}) \mod \beta^{n+r-k}$ 12: $U \leftarrow U + Q_r \beta^{r-(k+1)}$ 13: if $W_{r-k} < 0$ then $W_{r-k} \leftarrow W_{r-k} + \beta^{r-k} V$, $U \leftarrow U - \beta^{r-k}$ 14: $r \leftarrow r - k$ 15: $Q_r \leftarrow \text{ShortMul}(W_r \text{ div } \beta^{n+r-(k+1)}, I, k+1)$ 16: $U \leftarrow U + (Q_r \operatorname{div} \beta^{k+1-r})$ < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Theorem

Assuming $n + 8 < \beta/2$ and $\ell \le \sqrt{n/2}$, Algorithm FoldDiv(ℓ) returns an approximation U of $Q = \lfloor W/V \rfloor$, with error less than 2n.

Algorithm ShortMul is implemented in GNU MPFR since version 2.2.0 (2005)

Extended to the MPFR squaring operation in 2010

Algorithm ShortDiv is available in GNU MPFR since revision 7191

Algorithm FoldDiv is not (yet) implemented since it requires a middle-product routine, which is not (yet) provided by GMP

▲御 ▶ ▲ 臣 ▶ ▲ 臣 ▶ 二 臣

Conclusion

Our contributions :

- two variants of Mulders' short product and short division for integers, with detailed description and rigorous error analysis
- a detailed description and rigorous error analysis of the *ℓ*-fold division for integers
- we get a 10% speedup, and more speedup can be obtained for FoldDiv, by using a Toom-3 middle product, a faster (approximate) inverse based on the same ideas, ...

Benchmarks are a good way to improve software tools !

Still to do : design an approximate inverse using the $\ell\text{-fold}$ algorithm

Adapt the FoldDiv algorithm for an approximate inverse and update the error analysis
